

Bitcode

IP-Recycling — Design-Partner Kit

From thesis to signed pilot · the offer, the pilot, the moat-safety rubric, and the outreach · DRAFT for founder review.

1 · The offer, in four sentences

Most of your codebase is not your moat — it is infrastructure, integrations, tooling, and retired features that cost money to keep and earn nothing. Bitcode turns that idle non-moat code into measured, obfuscated, co-owned DataPacks and sells the knowledge in them to the companies training AI — the buyers paying billions for exactly this class of data. You keep ownership, you keep using the code, your secrets never leave, and you choose your payout in cash, \$BTD, or both. The pilot proves it on two or three repositories you already consider safe, in weeks, at zero engineering lift beyond a review.

2 · Who we want as a design partner

Criterion	Why
Successful software company, meaningful codebase	The thesis is about winners monetizing surplus — not distress sales. Scale makes the non-moat share large.
An engaged CTO or VP Eng	The moat-safety call is an engineering judgment; the pilot lives or dies on one respected internal sponsor.
Clean IP ownership on candidate repos	Rights-integrity at deposit must be simple; work-for-hire, no encumbering third-party terms.
Willing to be a (possibly anonymized) case study	The pilot's product is proof: realized revenue + zero exposure, published.
Bonus: a recently pivoted or sunset product line	Dead code is the easiest first deposit — value with zero competitive anxiety.

3 · The pilot — three phases, about six weeks

Phase 1 · Scope (week 1–2). Together we pick 1–3 non-moat repositories, run the moat-safety rubric below, and mark obfuscations (what to withhold). Legal confirms rights; the CTO signs the scope. Bitcode commits: nothing outside the marked scope is ever read.

Phase 2 · Deposit & measure (week 3–4). The partner connects the repos; Bitcode synthesizes obfuscated DataPacks and measures them — the full absolute catalogue with honesty statuses, material identity, and a measure report. The partner receives the depositor review artifact (measurements, patch plan, honesty counts — never raw bodies exposed) and verifies the zero-exposure guarantee against their own scan.

Phase 3 · Market (week 5–6 and onward). Approved packs are admitted to the Depository, discoverable by measured facets, and available to Needs. First settlements pay out per the partner's election (cash / \$BTD split). We co-publish the case study: what was deposited, what it measured, what it earned, and the exposure result — anonymized if preferred.

What the partner gets: a measured map of their own codebase (the absolute catalogue is a legibility product in itself), a new zero-marginal-cost revenue line, founding-supply pricing power, and first claim on the case-study halo. **What Bitcode gets:** real enterprise supply, the ROI case study the IP-recycling thesis needs, and a named (or anonymized) reference.

4 · The moat-safety rubric (what is safe to deposit)

The rubric gives the people who must say yes — CTO, security, legal — a defensible framework. Engineering tags, security scans, legal confirms, CTO signs.

Class	Contents	Posture
GREEN	Build & CI tooling, test harnesses, infrastructure code, integrations & API clients, data pipelines, utilities/glue, framework wrappers, deprecated features, sunset product lines	Deposit. Rivals already have equivalents; firms routinely open-source this class for free — selling it obfuscated is strictly less exposure.
YELLOW	Non-differentiating domain logic, internal frameworks, performance work not core to the product's edge	Case-by-case: deposit with heavier obfuscation, or hold for a later phase.
RED	Crown-jewel algorithms and differentiating logic; anything security-posture-revealing; third-party-encumbered code; anything containing secrets or personal data	Never deposited. Secrets/PII are also machine-gated by Bitcode regardless of tagging — verified-detector scans, fail-closed.

Defense in depth: the rubric is the human layer; Bitcode's own gates (obfuscation boundary, verified secret/PII scans, fail-closed validation, source-safe measurement — only measurements and metadata ever surface pre-payment) are the machine layer beneath it. A tagging mistake does not become an exposure.

5 · Objections, answered in one line each

“It helps competitors.” Buyers are AI labs training models, not competitors cloning products — and non-moat code confers no edge they lack.

“It's a security risk.” Obfuscation plus fail-closed machine gates; only measured, permitted material is ever exposed.

“Our code is an asset we should keep.” The non-moat share is a maintenance liability earning \$0; co-ownership means you keep it and it finally earns.

“Who buys plumbing?” Labs, at scale — ordinary production code is a coding model's textbook, and rights-clean beats scraped.

“Reputation.” Monetizing idle non-core assets is ordinary capital allocation, and the deposit can be fully private.

6 · Outreach email (draft)

Subject: The code you'd open-source anyway

[Name] —

AI labs are paying extraordinary sums for rights-clean production code:

Meta put \$14.3B into Scale, Anthropic paid \$1.5B for training on the wrong data. What they actually want is unglamorous, working code — build tooling, integrations, pipelines, retired features. The class of code you'd open-source without blinking. Never the crown jewels.

[1 line on why them — e.g.: You sunset <product> last year; that codebase is exactly this.]

I built Bitcode to make that sellable without making it public. Code

becomes measured, obfuscated assets: buyers see scores and metadata, never source. Secrets never leave – machine-enforced, not promised. You keep ownership, keep using everything, and get paid per sale in ETH, BTC, or SOL.

Before launch I'm taking a handful of design partners: 2–3 repos you already consider safe, about six weeks, nothing from your team beyond a scoping review. In exchange – founding-supply terms, a measured map of your codebase, and first position in the market.

The safety rubric is the part worth interrogating, so I'd start there. Thirty minutes, with your CTO if you like?

7 · Pilot success criteria

Measured, so the case study writes itself: (1) N repositories scoped and rubric-signed; (2) all deposited packs catalog-complete with deep or thin measure mode — zero expanded-fill presented as measured; (3) zero exposure incidents, verified by the partner's own scan of the review artifact; (4) first settlements and realized payout under the partner's election; (5) a publishable before/after: idle code → measured, listed, earning.
